Remaining risks after completed validation

10 October 2026. The user-authorized bounded GPU experiments have completed. Earlier no-go decisions in archived preflight files describe historical resource/input states and are superseded by this execution record.

Concern	Current outcome	Remaining limitation
Innovation	Complete 300-object equal-budget matrix; bounded new bake benefit; native second interface	Layer/time scheduling is prior work. No new general algorithm, selector or universal C3 optimum; R2.1 remains a material risk
Practical appearance	New ten-object GT-256-calibrated unseen-view pilot, all controls, full objects, failure example and real video	Only ten inputs eligible, below target twenty; unlit base color; no validated seam/PBR endpoint; persistent Tire color failure
Second backbone	New fifty-object native-camera matrix and official/deployed/default identity checks	Primary not separated; feature-scale interface differs from GeoTex; thirteen white-albedo targets retained
Historical headline	Fresh C +0.52 dB C3–GFL is bounded and distinct from historical +0.96	Historical main checkpoint/endpoint not fully reconstructed
Statistics	Object-paired intervals; explicit primary and Holm secondary families; extracted archive reproduces numbers	Pointwise intervals; no equivalence/non-inferiority claim; source cohort already seen in image domain
FAC	Negative historical re-examination preserved; available code/config supplied	Training manifest/seed/output linkage missing; no full replay
Defaults/calibration	REPEAT, pole masks, scalar alpha and GT-256 corrected	GeoTex Constant 1.0 is capped, not unset-scale native output; old N=7 quality invalid
Submission	Clean/marked/Supp/response/source/reproduction/video locally assembled	Author must verify metadata, editorial attachments and final declarations before upload; no journal submission made

No additional schedules, searches or training are queued. All valid adverse results remain. Raw assets/weights are not publicly redistributed.
