

R1 color failure — paired RGB baseline comparison

Failure-enriched development diagnostics: 26 objects (six exact 01549 Fig. 4/6 cases + 20 reused Fresh-C panels).

All prediction panels are complete 3-row × 2-column grids of six RGB views. The PNG sources are preserved separately at 512×768.

Protocol: checkpoint 0618d6b2...e0114c0 · unique6 views [0,15,12,16,13,14] · 50 Euler steps · seed 42 + source-list index.

Historical Fig. 4/6 outputs were regenerated under the locked runner; Fresh-C outputs use paired current reruns because archived PNGs did not reproduce byte-for-byte.

Per-method descriptive results

Condition	Mean object CIEDE2000 ↓	Strict Lab flags
No Adapter	36.66	0/26
GFL	17.00	0/26
GFH	21.92	0/26
C3	18.78	0/26
Generic Linear	21.58	0/26
LLH	20.59	0/26

CIEDE2000 is the equal-weight mean of six per-view foreground scores. Purple flag was frozen as mean $\Delta a^* \geq 5$, mean $\Delta b^* \leq -5$, and mean CIEDE2000 ≥ 5 .

No object crossed this strict vector-shift flag. That threshold result does not rule out a visible pink/lavender cast; continuous color error and the panel-by-panel visual review are reported separately.

These selected and previously viewed objects are diagnostics, not an independent confirmation cohort. Colors are measured from the saved RGB grids in sRGB-to-Lab space.

Interpretation is limited to 2D generated RGB. UV projection, texture baking, glTF export, and unseen-view rendering are not measured by this comparison.

Visual pages follow: each object row shows Reference / No Adapter / GFL / GFH / C3 / Generic Linear / LLH. No panel is cropped or recolored.

See ROOT_CAUSE_EXPERIMENT.md for pipeline audit, residual intervention results, and limits.
