Sixth-round reviewer response addendum

We add a source-derived camera-contract audit and complete native-loop implementation checks. The official inference and bake permutations are inverses; actual metadata from all ten baking objects matches the nominal directions after conditioning-anchor rotation. This does not verify pole-image roll, pixel registration or generated-view correctness. Immutable official source snapshots and per-object records are provided.

Loading the frozen GeoTex weights while clearing geometry reproduces both prior bare-native base grids bitwise. The subsequent sixteen-call matrix keeps native512/CFG2/EulerAncestral inference fixed, with trained256 geometry encoding and the frozen historical schedules. Actual hooks confirm all nine reference-write skips/read corrections, common within-object inputs, features, initial latents and outer-call RNG states. Geometry broadcasts to both CFG branches; this branch policy and the unresolved encoding-resolution compatibility are explicit.

All real outputs are retained. Geometry-enabled remote outputs lose most reference content, and several tire outputs blur detail. These are seen-case negative findings, not a validated quality repair or independent deployment result. Historical C3 and scalar Fixed Mean do not share every layer budget in this native diagnostic; no matched-budget claim is made for that contrast. The failed pre-loading registry import is preserved separately. S24, the main text and abstract disclose the practical appearance limitation. Novelty and independent native-deployment quality remain unresolved.
